

screensaver_moving_logo_widget

TouchGFX widget for contest.

Moves a logo over the entire display. Bounces against the edges of the display.

How to use

in the export folder you can find the .tpkg file. You can import that in your TouchGFX project.

If you add the widget anywhere to a screen it will automatically adjust itself to the screen size.

Status of code

The code work (tested on STM32H735G and in simulator), but there are several features I would like to add:

- ability to hide widget and disable the animation to save resources**
- configure speed of animation from user application**
- configure framerate of hardware so that speed of animation on hardware matches that of simulation**
- callback on bounce so image can be changed on bounce**
- random start location and direction (the hardware would need a random source for the seed of the PRNG or would need to have a true hardware RNG)**
